

Matrix Introduction

Stressors → Habitats and Populations → Ecosystem Services

Pressure → State → Impact

Complex Social- Ecological Systems

Environmental planning and management problems are often directed at protecting human health, well-being, or ecosystem services and involve complex, coupled social and ecological systems

Decision-making in complex systems requires an adequate understanding (model) of the system

Time and space
scales

Shared
understanding

Anticipate outcomes
prior to decisions

Complex Social- Ecological Systems

For model development,
there is a scientific
method

Data and literature
synthesis
Field and Lab Studies
Aggregation and
synthesis for a model

However, model
development based on
the scientific method
often lags decision time-
frames

Too many potential
social-ecological
interactions
Funding is too slow
or insufficient to
address the system

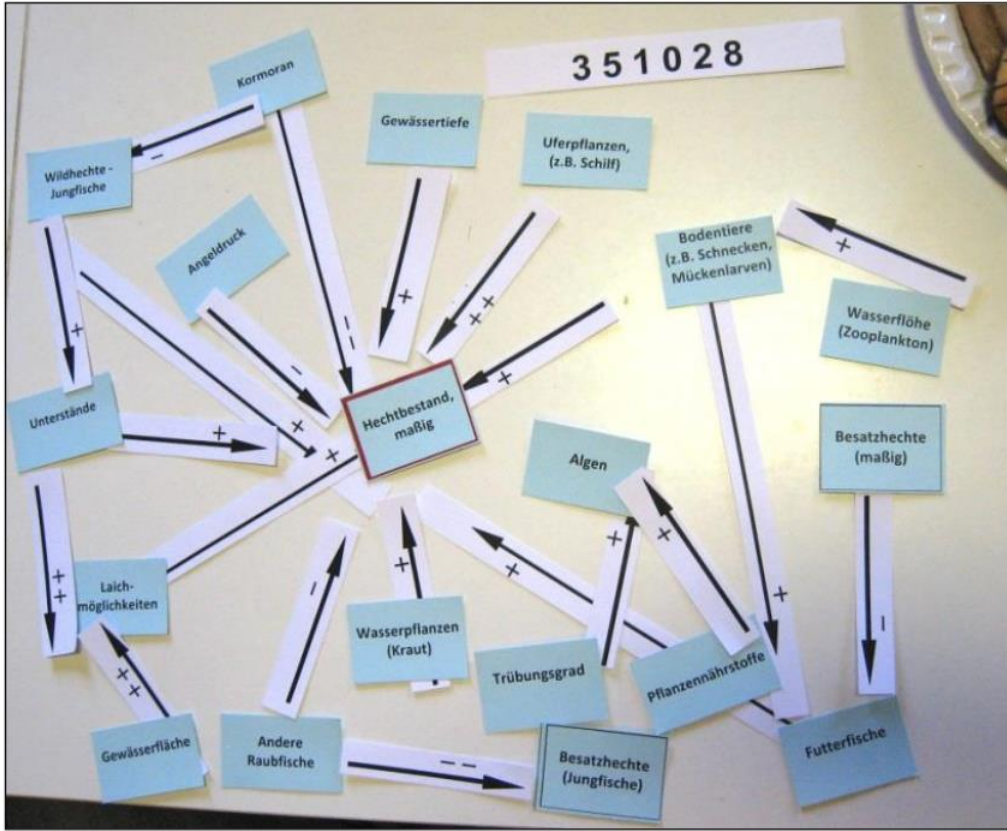

We need another way ...

Wisdom of stakeholder crowds in complex social-ecological systems

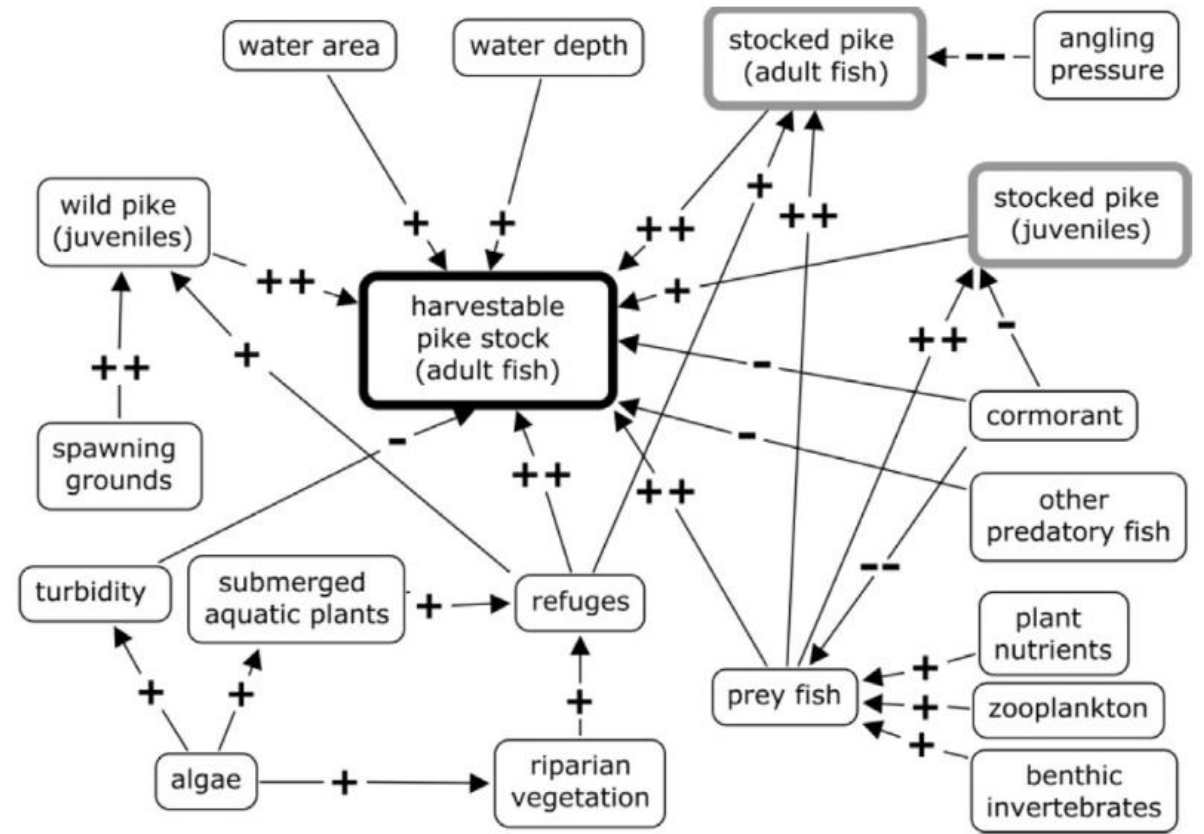

Aminpour et al. (2020)

“Wisdom of the Crowds”

- First demonstrated over a century ago when crowds estimate the weight of a dead ox. The average estimate was remarkably close to the actual weight
- Over the last several decades, has been used for increasingly complex problems
- Aminpour et al. (2020) use Wisdom of the Crowds for a complex social-ecological system involving the pike fishery in Germany
 - Asked stakeholders to produce a quantitative (quasi) causal model describing pike ecology and fishery management
 - Causal models produced by a diverse set of stakeholders were nearly identical to the models produced by an expert panel

Aminpour et al. (2020)

Gray et al. (2015)

If you
remember back
to 2012, we did
something like
this for the
2013-2018
CCMP

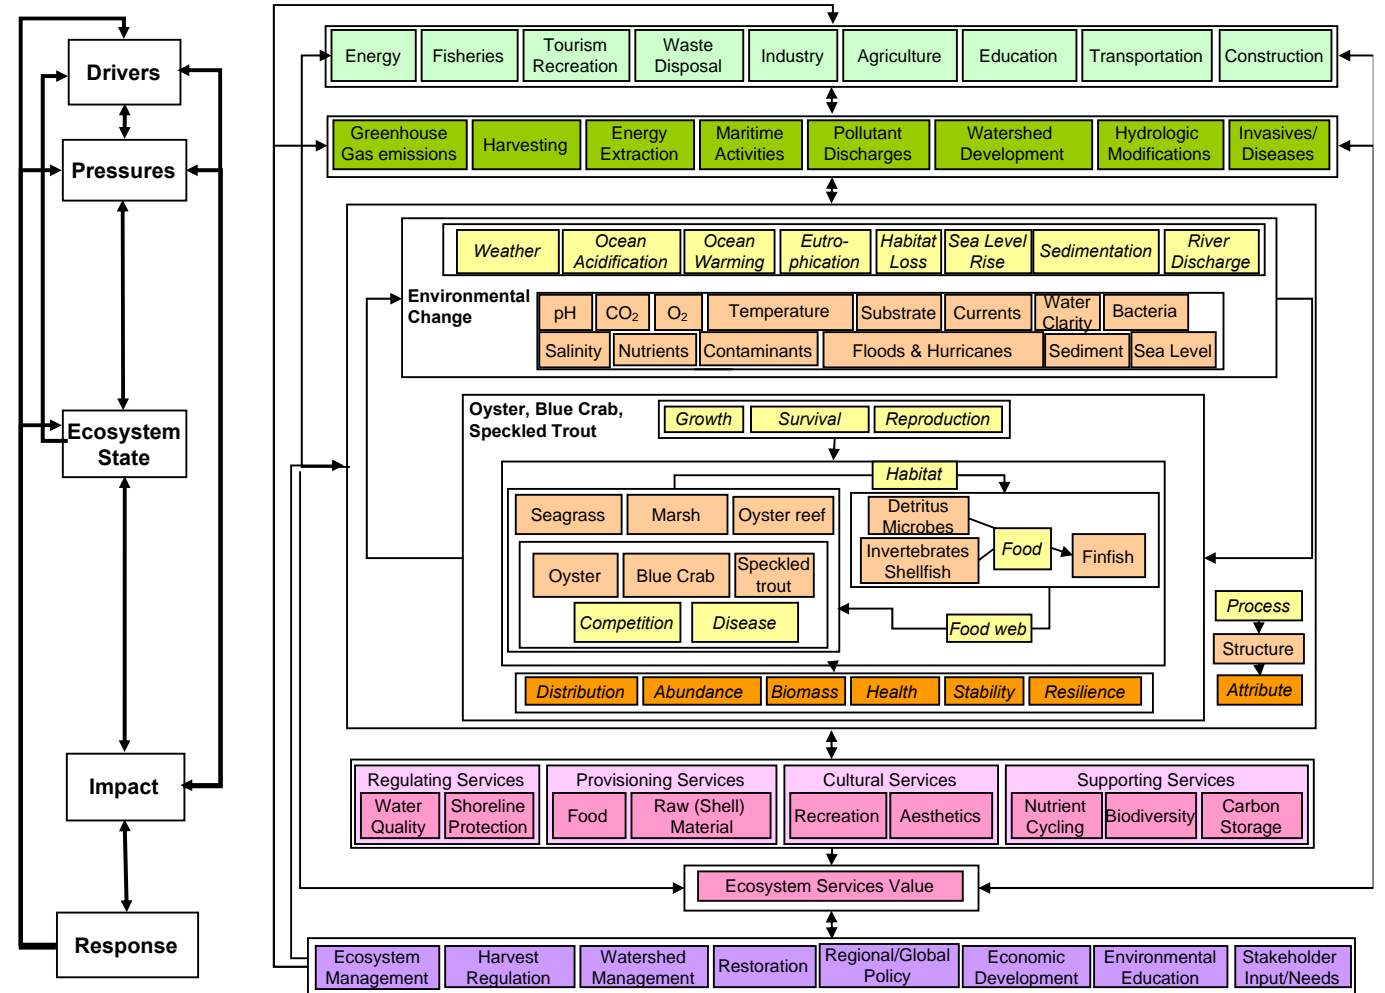

- We used stakeholder groups to develop conceptual models that linked stressors, status, and management related to the six priority areas that bay stakeholders valued the most
 - Access
 - Beaches and Shoreline
 - Fish
 - Heritage and Culture
 - Environmental Health and Resilience
 - Water Quality

Going forward, what will this look like?

One possibility: DPSIR approach

Example DPSIR for Oysters, Blue Crab, and Speckled Trout (Lehrter et al. NOAA RESTORE proposal)

System Conceptual Model

Today, we begin discussing an approach for linking environmental pressures (stressors) to habitats and populations to ecosystem services based on the issue of coal ash

- We are not experts on coal ash, but we are scientists and managers and have collective wisdom
- Development of causal model is rooted in a Driver → Pressure → State → Impact → Response framework (DPSIR) (Bradley and Yee 2015)
- We would like to hear from the SAC about this approach
- If the SAC agrees, we plan to use this approach to develop system level models for several pertinent issues in Mobile Bay
